Abstract
This document analyzes the security properties of the FIDO UAF and U2F families of protocols.

Status of This Document
This section describes the status of this document at the time of its publication. Other documents may supersede this document. A list of current FIDO Alliance publications and the latest revision of this technical report can be found in the FIDO Alliance specifications index at https://www.fidoalliance.org/specifications/.

This document was published by the FIDO Alliance as a Review Draft. This document is intended to become a FIDO Alliance Proposed Standard. If you wish to make comments regarding this document, please Contact Us. All comments are welcome.

This is a Review Draft Specification and is not intended to be a basis for any implementations as the Specification may change. Permission is hereby granted to use the Specification solely for the purpose of reviewing the Specification. No rights are granted to prepare derivative works of this Specification. Entities seeking permission to reproduce portions of this Specification for other uses must contact the FIDO Alliance to determine whether an appropriate license for such use is available.

Implementation of certain elements of this Specification may require licenses under third party intellectual property rights, including without limitation, patent rights. The FIDO Alliance, Inc. and its Members and any other contributors to the Specification are not, and shall not be held, responsible in any manner for identifying or failing to identify any or all such third party intellectual property rights.

THIS FIDO ALLIANCE SPECIFICATION IS PROVIDED “AS IS” AND WITHOUT ANY WARRANTY OF ANY KIND, INCLUDING, WITHOUT LIMITATION, ANY EXPRESS OR IMPLIED WARRANTY OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.

   7.1  Threats to Client Side
      7.1.1  Exploiting User’s pattern matching weaknesses
      7.1.2  Threats to the User Device, FIDO Client and Relying Party Client Applications
      7.1.3  Creating a Fake Client
      7.1.4  Threats to FIDO Authenticator
      7.1.5  Threats to Relying Party
      7.1.5.1  Threats to FIDO Server Data

1. Notation

Type names, attribute names and element names are written as code.
String literals are enclosed in "", e.g. "UAF-TLV".
In formulas we use "|" to denote byte wise concatenation operations.
UAF specific terminology used in this document is defined in [FIDOglossary].

1.1 Key Words

The key words "must", "must not", "required", "shall", "shall not", "should", "should not", "recommended", "may", and "optional" in this document are to be interpreted as described in [RFC2119].

2. Introduction

This document analyzes the security properties of the FIDO UAF and U2F families of protocols. Although a brief architectural summary is provided below, readers should familiarize themselves with the the FIDO Glossary of Terms [FIDOglossary] for definitions of terms used throughout. For technical details of various aspects of the architecture, readers should refer to the FIDO Alliance specifications in the Bibliography.

2.1 Intended Audience

This document assumes a technical audience that is proficient with security analysis of computing systems and network protocols as well as the specifics of the FIDO architecture and protocol families. It discusses the security goals, security measures, security assumptions and a series of threats to FIDO systems, including the users' computing environment, the Relying Party's computing environment, and the supply chain, including the vendors of FIDO components.

3. Attack Classification

The following attacks all result in user impersonation if successful. However, they have distinguishing characteristics which we use as the basis for attack classification:

1. Automated attacks not focused on the users systems, which affect the user.
2. Automated attacks which are focused on the users' device and which are performed once and lead to the ability to impersonate the user on
an on-going basis without involving him or his device directly.

3. Automated attacks which involve the user or his device for each successful impersonation.

4. Automated attacks to sessions authenticated by the user.

5. Not automatable attacks to the user or his device which are performed once and lead to the ability to impersonate the user on an on-going basis without involving him or his device directly.

6. Not automatable attacks to the user or his device which involve the user or his device for each successful impersonation.

Counter Measures

<table>
<thead>
<tr>
<th>Counter Project</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use robust &amp; spoofing resistant user verification.</td>
<td>Physically attacking user devices <strong>steal data</strong> for impersonation.</td>
</tr>
<tr>
<td>Use SE based key protection.</td>
<td>Physically attacking user devices <strong>misuse them</strong> for impersonation.</td>
</tr>
<tr>
<td>Use TEE or SE based key protection. Use HW based user verification.</td>
<td>Remotely attacking lots of user devices <strong>steal data</strong> for impersonation.</td>
</tr>
<tr>
<td>Use TEE confirmation with TEE based transaction display.</td>
<td>Remotely attacking lots of user devices <strong>misuse them</strong> for impersonation.</td>
</tr>
<tr>
<td>Use asymmetric crypto, e.g. FIDO</td>
<td>Remotely attacking central servers <strong>steal data</strong> for impersonation.</td>
</tr>
</tbody>
</table>

Fig. 2 Attack Classes

The first four attack classes are considered scalable as they are nominally automatable. The attack classes 5 and 6 are not automatable; they involve some kind of manual/physical interaction of the attacker with the user or his device. We will attribute the threats analyzed in this document with the related attack class (AC1 – AC6).

NOTE

1. FIDO uses asymmetric cryptography to protect against AC1. This gives control back to the user, i.e. when using good random numbers, the user’s authenticator can make breaking the key as hard as the underlying factoring (in the case of RSA) or discrete logarithm (in the case of DSA or ECDSA) problem.

2. Once counter-measures for this kind of attack are commonly in place, attackers will likely focus on another attack class.

3. The numbers at the attack classes do not imply a feasibility ranking of the related attacks, e.g. it is not necessarily more difficult to perform (AC4) than it is to perform (AC3).

4. The user has almost no influence on the feasibility of attack class (AC1). This makes this attack class really bad.

5. The concept of physical security (i.e. “protect your Authenticator from being stolen”), related to attack classes (AC5) and (AC6) is much better internalized by users than the concept of logical security, related to attack classes (AC2), (AC3) and (AC4).

6. In order to protect against misuse of authenticated sessions (e.g. MITM attacks), the FIDO Authenticator must support the concept of transaction confirmation and the relying party must use it.

7. For an attacker to succeed in impersonating the user, any attack class is sufficient.

Attack Classes

We define the term scalable attack as any attack where the marginal cost of adding an additional target is near zero and which leads to violations of the FIDO security goals.

NOTE

The first four attack classes (AC1, AC2, AC3, and AC4) are considered scalable. The last two attack classes (AC5 and AC6) are not scalable and are performed as one-off user/Relying Party style compromises. We will attribute the threats analyzed in this document with the related attack class (AC1 – AC6).

AC1

Attacks not focused on the users’ devices and which lead to violations of FIDO security goals. (e.g., compromise of a Relying Party FIDO database and successful decryption of wrapped keys within the database, phishing, MITM attacks, etc.).

AC2
Scalable attacks involving the Authenticator which, once performed, lead to the ability to violate FIDO security goals on an ongoing basis without later involving the users or their devices directly (e.g., a scalable attack on FIDO Authenticators that recovers the user private keys, allowing the attacker to impersonate the users on an ongoing basis).

**AC3**

Scalable attacks which involve the user or his device for each instance where the FIDO security goals are violated (e.g., a scalable attack that requires the Authenticator for each successful impersonation).

**AC4**

Scalable attacks on sessions authenticated by the user which violate FIDO security goals.

**AC5**

Non-scalable attacks involving the Authenticator which, once performed, lead to the ability to violate FIDO security goals on an ongoing basis without later involving the users or their devices directly (e.g., a non-scalable attack on FIDO Authenticators that recovers the user private keys, allowing the attacker to impersonate the users on an ongoing basis).

**AC6**

Non-scalable attacks which involve the user or his device for each instance where the FIDO security goals are violated (e.g., a non-scalable attack that requires the Authenticator for each successful impersonation).

**NOTE**

At this time we are not explicitly addressing classes of physical attacks on the authenticator that may lead to reduced security if the legitimate user uses the authenticator after the attacker having physical access to it.

4. FIDO Security Goals

In this section the specific security goals of FIDO are described. The FIDO UAF protocol [UAFProtocol] and U2F protocol [U2FOverview] support a variety of different FIDO Authenticators. Even though the security of those authenticators varies, the UAF protocol and the FIDO Server should provide a very high level of security - at least on a conceptual level. In reality it might require a FIDO Authenticator with a high security level in order to fully leverage the FIDO security strength.

**NOTE**

In certain environments the overall security of the explicit authentication (as provided by FIDO) is less important, as it might be supplemented with a high degree of implicit authentication or the application doesn't even require a high level of authentication strength.

The FIDO U2F protocol [U2FOverview] supports a more constrained set of Authenticator capabilities. It shares the same security goals as UAF, with the exception of SG-14 Transaction Non-Repudiation.

The FIDO protocols have the following security goals:

**[SG-1]**

- **Strong User Authentication:** Authenticate (i.e. recognize) a user and/or a device to a relying party with high (cryptographic) strength.

**[SG-2]**

- **Credential Guessing Resilience:** Provide robust protection against eavesdroppers, e.g. be resilient to physical observation, resilient to targeted impersonation, resilient to throttled and unhindered guessing.

**[SG-3]**

- **Credential Disclosure Resilience:** Be resilient to phishing attacks and real-time phishing attack, including resilience to online attacks by adversaries able to actively manipulate network traffic.

**[SG-4]**

- **Unlinkability:** Protect the protocol conversation such that any two relying parties cannot link the conversation to one user (i.e., be unlinkable).

**[SG-5]**

- **Verifier Leak Resilience:** Be resilient to leaks from other relying parties. I.e., nothing that a verifier could possibly leak can help an attacker impersonate the user to another relying party.

**[SG-6]**

- **Authenticator Leak Resilience:** Be resilient to leaks from other FIDO Authenticators. I.e., nothing that a particular FIDO Authenticator could possibly leak can help an attacker to impersonate any other user to any relying party.

**[SG-7]**

- **User Consent:** Notify the user before a relationship to a new relying party is being established (requiring explicit consent).

**[SG-8]**

- **Limited PII:** Limit the amount of personal identifiable information (PII) exposed to the relying party to the absolute minimum.

**[SG-9]**

- **Attestable Properties:** Relying Party must be able to verify FIDO Authenticator model/type (in order to calculate the associated risk).

**[SG-10]**

- **DoS Resistance:** Be resilient to Denial of Service Attacks. I.e., prevent attackers from inserting invalid registration information for a legitimate user for the next login phase. Afterward, the legitimate user will not be able to login successfully anymore.

**[SG-11]**

- **Forgery Resistance:** Be resilient to Forgery Attacks (Impersonation Attacks). I.e., prevent attackers from attempting to modify intercepted communications in order to masquerade as the legitimate user and login to the system.

**[SG-12]**

- **Parallel Session Resistance:** Be resilient to Parallel Session Attacks. Without knowing a user’s authentication credential, an attacker can masquerade as the legitimate user by creating a valid authentication message out of some eavesdropped communication between the user and the server.

**[SG-13]**

- **Forwarding Resistance:** Be resilient to Forwarding and Replay Attacks. Having intercepted previous communications, an attacker can impersonate the legal user to authenticate to the system. The attacker can replay or forward the intercepted messages.

**[SG-14]** (not covered by U2F)

- **Transaction Non-Repudiation:** Provide strong cryptographic non-repudiation for secure transactions.

**[SG-15]**

- **Respect for Operating Environment Security Boundaries:** Ensure that registrations and private key material as a shared system resource is appropriately protected according to the operating environment privilege boundaries in place on the FIDO user device.

**[SG-16]**

- **Assessable Level of Security:** Ensure that the design and implementation of the Authenticator allows for the testing laboratory / FIDO Alliance to assess the level of security provided by the Authenticator.

**NOTE**

For a definition of the phrases printed in italics, refer to [QuestToReplacePasswords] and to PasswordAuthSchemesKeyIssues]

4.1 Assets to be Protected

Independent of any particular implementation, the FIDO protocols assume some assets to be present and to be protected.
5. FIDO Security Measures

NOTE

Particular implementations of FIDO Clients, Authenticators, Servers and participating applications may not implement all of these security measures (e.g. Secure Display, [SM-10] Transaction Confirmation) and they also might (and should) implement additional security measures.

NOTE

The U2F protocol lacks support for [SM-5] Secure Display, [SM-10] Transaction Confirmation, has only server-supplied [SM-8] Protocol Nonces, and [SM-3] Authenticator Class Attestation is implicit as there is only a single class of device.

[SM-1] (U2F + UAF)

Key Protection: Authentication key is protected against misuse. Misuse means any use violating the FIDO specification or the details given in the Metadata Statement. Before a key can be used, it requires the User to unlock it using the user verification method specified in the Authenticator Metadata Statement (Silent Authenticators do not require any user verification method).

[SM-2] (U2F + UAF)

Unique Authentication Keys: Cryptographic authentication key is specific and unique to the tuple of (FIDO Authenticator, User, Relying Party).

[SM-3] (U2F + UAF)

Authenticator Class Attestation: Hardware-based FIDO Authenticators support authenticator attestation using an attestation key using one of the FIDO specified attestation types and algorithms. Each relying party receives regular updates of the trust store (through the FIDO Metadata Service).

[SM-4] (UAF)

Authentication Status Checking: Relying Parties can download latest known status of authenticators included in the FIDO Metadata Service. The FIDO Server should take this information into account. Authenticator manufacturers should notify the FIDO Alliance about compromised authenticators. In the case of FIDO certified authenticators, such notification might even be mandatory.

[SM-5] (UAF)

User Consent: FIDO Client implements a user interface for getting user’s consent on any actions (except authentication with silent authenticator) and displaying RP name (derived from server URL).

[SM-6] (U2F + UAF)

Cryptographically Secure Verifier Database: The relying party stores only the public portion of an asymmetric key pair, or an encrypted key handle, as a cryptographic authentication key reference.

[SM-7] (U2F + UAF)

Secure Channel with Server Authentication: The TLS protocol with server authentication or a transport with equivalent properties is used as transport protocol for UAF. The use of https is enforced by a browser or Relying Party application.

[SM-8] (UAF)

Protocol Nonces: Both server and client supplied nonces are used for UAF registration and authentication. U2F requires server supplied nonces.

[SM-9] (U2F + UAF)

Authenticator Certification: The FIDO Metadata Service includes the Authenticator certification status.

[SM-10] (UAF)

Transaction Confirmation (WYSIWYS): Secure Display (WYSIWYS) (optionally) implemented by the FIDO Authenticators is used by FIDO Client for displaying relying party name and transaction data to be confirmed by the user.

[SM-11] (U2F + UAF)

Round Trip Integrity: FIDO server verifies that the transaction data related to the server challenge received in the UAF message from the FIDO client is identical to the transaction data and server challenge delivered as part of the UAF request message.

[SM-12] (U2F + UAF)

Channel Binding: Relying Party servers may verify the continuity of a secure channel with a client application.

[SM-13] (UAF)

Key Handle Access Token: Authenticators not intended to roam between untrusted systems are able to constrain the use of registration keys within the privilege boundaries defined by the operating environment of the user device (per-user, or per application, or per-user + per-application as appropriate).

[SM-14] (U2F + UAF)

AppID Separation: A Relying Party can declare the application identities allowed to access its registered keys, for operating environments on user devices that support this concept.

[SM-15] (U2F + UAF)

Signature Counter: Authenticators send a monotonically increasing signature counter that a Relying Party can check to possibly detect cloned authenticators.

[SM-16] (U2F + UAF)

Use of strong, modern Cryptographic Primitives: The FIDO specifications stipulate the use of strong, modern cryptographic primitives helping to ensure the overall security of conformant FIDO implementations. The FIDO Authenticator certification program defines the "Allowed Cryptography List" for allowed cryptographic primitives to be used in FIDO certified authenticators.

[SM-17] (U2F + UAF)

Resistance to Side Channel Attacks.

[SM-18] (U2F + UAF)

Resistance to Injected Faults in Cryptographic Functions. This security measure purely deals with the cryptographic functions, as compared to the much more general [SM-28].
[SM-19] (UAF) Bounded Probability of a Birthday Collision. For randomly generated nonces, the total number of nonces that can be generated is limited to bound the probability of a birthday collision of generated values.

[SM-25] (U2F + UAF) Input Data Validation: Malformed or maliciously crafted input data does not result in unexpected Authenticator behavior.

[SM-26] (U2F + UAF) Protection of user verification reference data and biometric data.

[SM-28] (U2F + UAF) Resistance to Remote Timing Attacks: No leakage of secret information to remote entities via variation of operation execution time.

6. FIDO Security Assumptions

In this section, we enumerate the assumptions we are making regarding the security characteristics of the operating environment components on which a FIDO implementation depends.
7.1.2 Threats to Client Side

### 7.1.1 Exploiting User’s pattern matching weaknesses

<table>
<thead>
<tr>
<th>Threat Description</th>
<th>Violates</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>T-1.1.1</strong> Homograph Mis-Registration</td>
<td><strong>SG-1</strong></td>
</tr>
<tr>
<td>The user registers a FIDO authentication key with a fraudulent web site instead of the genuine Relying Party.</td>
<td></td>
</tr>
<tr>
<td><strong>Consequences:</strong> The fraudulent site may convince the user to disclose a set of non-FIDO credentials sufficient to allow the attacker to register a FIDO Authenticator under its own control, at the genuine Relying Party, on the users’ behalf, violating [SG-1] Strong User Authentication.</td>
<td></td>
</tr>
<tr>
<td><strong>Mitigations:</strong> Disclosure of non-FIDO credentials is outside of the scope of the FIDO security measures, but Relying Parties should be aware that the initial strength of an authentication key is no better than the identity-proofing applied as part of the registration process.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Threat Description</th>
<th>Violates</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>T-1.1.2</strong> Homograph Mis-Authentication</td>
<td><strong>SG-1, SG-4</strong></td>
</tr>
<tr>
<td>The user accidentally browses to a fraudulent web site. The attacker tries to act as man-in-the-middle (MITM) and requests the user to authenticate. In the case of username/password based authentication this is a typical phishing attack.</td>
<td></td>
</tr>
<tr>
<td><strong>Consequences:</strong> The FIDO subsystem will determine that either (a) no FIDO authenticator has been registered with the fraudulent site or (b) it will use the FIDO Uauth key registered to the fraudulent site - which is different from the Uauth key for the relying party’s site.</td>
<td></td>
</tr>
<tr>
<td><strong>Mitigations:</strong> FIDO inherently ties keys to the relying party (formally identified by the AppID, and authenticated by TLS and the CA infrastructure).</td>
<td></td>
</tr>
</tbody>
</table>

7.1.2 Threats to the User Device, FIDO Client and Relying Party Client Applications

<table>
<thead>
<tr>
<th>Threat Description</th>
<th>Violates</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>T-1.2.1</strong> FIDO Client Corruption</td>
<td><strong>SA-4</strong></td>
</tr>
<tr>
<td>Attacker gains ability to execute code in the security context of the FIDO Client.</td>
<td></td>
</tr>
<tr>
<td><strong>Consequences:</strong> Violation of [SA-4].</td>
<td></td>
</tr>
<tr>
<td><strong>Mitigations:</strong> When the operating environment on the FIDO user device allows, the FIDO Client should operate in a privileged and isolated context under [SA-2] to protect itself from malicious modification by anything outside of the Trusted Computing Base.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Threat Description</th>
<th>Violates</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>T-1.2.2</strong> Logical/Physical User Device Attack</td>
<td></td>
</tr>
<tr>
<td>Attacker gains physical access to the FIDO user device but not the FIDO Authenticator.</td>
<td></td>
</tr>
<tr>
<td><strong>Consequences:</strong> Possible violation of [SA-4] by installing malicious software or otherwise tampering with the FIDO user device.</td>
<td></td>
</tr>
<tr>
<td><strong>T-1.2.3</strong></td>
<td><strong>User Device Account Access</strong></td>
</tr>
<tr>
<td>-------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td><strong>AC3</strong></td>
<td>Attacker gains access to a user's login credentials on the FIDO user device. <strong>Consequences:</strong> Authenticators might be remotely abused, or weakly-verifying authenticators might be locally abused, violating [SG-1] Strong User Authentication and [SG-13] Transaction Non-Repudiation. Possible violation of [SA-4] by the installation of malicious software. <strong>Mitigations:</strong> Relying Parties can use [SM-9] Authenticator Certification and [SM-3] Authenticator Class Attestation to determine the nature of authenticators and not rely on weak, or weakly-verifying authenticators for high value operations.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>T-1.2.4</strong></th>
<th><strong>App Server Verification Error</strong></th>
<th><strong>Violates</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AC3</strong></td>
<td>A client application fails to properly validate the remote server identity, accepts forged or stolen credentials for a remote server, or allows weak or missing cryptographic protections for the secure channel. <strong>Consequences:</strong> An active network adversary can modify the Relying Party's authenticator policy and downgrade the client's choice of authenticator to make it easier to attack. An active network adversary can intercept or view FIDO messages intended for the Relying Party. It may be able to use this ability to violate [SG-12] Parallel Session Resistance, [SG-11] Forging Resistance or [SG-13] Forwarding Resistance. <strong>Mitigations:</strong> The server can verify [SM-8] Protocol Nonces to detect replayed messages and protect from an adversary that can read but not modify traffic in a secure channel. The server can mandate a channel with strong cryptographic protections to prevent message forgery and can verify a [SM-12] Channel Binding to detect forwarded messages.</td>
<td><strong>SG-11, SG-12, SG-13</strong></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>T-1.2.5</strong></th>
<th><strong>RP App Corruption</strong></th>
<th><strong>Violates</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AC3</strong></td>
<td>An attacker is able to obtain malicious execution in the security context of the Relying Party client application (e.g. via Cross-Site Scripting (XSS)) or abuse the secure channel or session identifier after the user has successfully authenticated. This is a client side attack. <strong>Consequences:</strong> The attacker is able to control the users' session, violating [SG-14] Transaction Non-Repudiation. <strong>Mitigations:</strong> The server can employ [SM-10] Transaction Confirmation to gain additional assurance for high value operations.</td>
<td><strong>SG-14</strong></td>
</tr>
</tbody>

<td>An adversary is able to obtain an authenticator's signed protocol response message. <strong>Consequences:</strong> The attacker attempts to replay the message to authenticate as the user, violating [SG-1] Strong User Authentication, [SG-13] Forwarding Resistance and [SG-12] Parallel Session Resistance. <strong>Mitigations:</strong> The server can use [SM-8] Protocol Nonces to detect replay of messages and verify [SM-11] Round Trip Integrity to detect modified messages.</td>
<td><strong>SG-1, SG-12, SG-13</strong></td>
</tr>
</tbody>
</table>
### 1.2.9 Malicious App

A user installs an application that represents itself as being associated with to one Relying Party application but actually initiates a protocol conversation with a different Relying Party and attempts to abuse previously registered authentication keys at that Relying Party.

**Consequences:** Adversary is able to violate [SG-7] User Consent by misrepresenting the target of authentication.

Other consequences equivalent to [T-1.2.5]

**AC3**

**Mitigations:** If a [SM-5] Transaction Confirmation Display is present, the user may be able to verify the true target of an operation.

If the malicious application attempts to communicate directly with an Authenticator that uses [SM-13] KeyHandleAccessToken, it should not be able to access keys registered by other FIDO Clients.

If the operating environment on the FIDO user device supports it, the FIDO client may be able to determine the application's identity and verify if it is authorized to target that Relying Party using a [SM-14] AppID Separation.

**SG-7**

### 1.2.10 Phishing Attack

A Phisher convinces the user to enter his PIN used for user verification into an application / web site disclosing the PIN to the Phisher. In the traditional username/password world this enables the attacker to successfully impersonate the user (to the relying party).

**Consequences:** None as the phisher additionally would need access to the Authenticator in order to pass user verification [SM-1]. In FIDO, the user verification PIN (if user verification is done via PIN) is not known to the relying party and hence isn't sufficient for user impersonation. If user verification is done using an alternative user verification method, this applies accordingly.

**AC2**

**Mitigations:** In FIDO, the Uauth.priv key is used to sign a relying party supplied challenge. Without (use) access to that key, no impersonation is possible.

**SG-1**

### 7.1.3 Creating a Fake Client

#### 1.3.1 Malicious FIDO Client

Attacker convinces users to install and use a malicious FIDO Client.

**Consequences:** Violation of [SA-4]

**AC3**

**Mitigations:** Mitigating malicious software installation is outside the scope of FIDO.

If an authenticator implements [SM-1] Key Protection, the user may be able to recover full control of their registered authentication keys by removing the malicious software from their user device.

When using [SM-10] Transaction Confirmation, the user sees the real AppIDs and transaction text and can decide to accept or reject the action.

**SA-4**

### 7.1.4 Threats to FIDO Authenticator

#### 1.4.1 Malicious Authenticator

Attacker convinces users to use a maliciously implemented authenticator.

**Consequences:** The fake authenticator does not implement any appropriate security measures and is able to violate all security goals of FIDO.

**AC2, AC3**

**Mitigations:** A user may be unable to distinguish a malicious authenticator, but a Relying Party can use [SM-3] Authenticator Class Attestation to identify and only allow registration of reliable authenticators that have passed [SM-9] Authenticator Certification.

A Relying Party can additionally rely on [SM-4] Authenticator Status Checking to check if an attestation presented by a malicious authenticator has been marked as compromised.

**SG-1**

### 1.4.2 Uauth.priv Key Compromise

Attacker succeeds in extracting a user's cryptographic authentication private key for use in a different context.

**Consequences:** The attacker could impersonate the user with a cloned authenticator that does not do trustworthy user verification, violating [SG-1].

**AC2**

**Mitigations:** [SM-1] Key Protection measures are intended to prevent this.

Each authentication private key is only used for one relying party.

Relying Parties can check [SM-9] Authenticator Certification attributes to determine the type of key protection in use by a given authenticator class.

Relying Parties can additionally verify the [SM-15] Signature Counter and detect that an authenticator has been cloned if it ever fails to advance relative to the prior operation.

**SG-1**

### 1.4.3 User Verification By-Pass

Attacker derives and uses the user's Uauth.priv key.

**Consequences:** The attacker could impersonate the user with a cloned authenticator that does not do trustworthy user verification, violating [SG-1].

**AC2**

**Mitigations:** [SM-1] Key Protection measures are intended to prevent this.

Each authentication private key is only used for one relying party.

Relying Parties can check [SM-9] Authenticator Certification attributes to determine the type of key protection in use by a given authenticator class.

Relying Parties can additionally verify the [SM-15] Signature Counter and detect that an authenticator has been cloned if it ever fails to advance relative to the prior operation.

**SG-1**

</tbody>
</table>
### Firmware Rollback

**Mitigations:** Proper robustness firmware update and verification method.

**Violates:** SG-1

**Consequences:** This might lead to successful attacks, e.g. T-1.4.9.

**Attacker might be able to install a previous and potentially buggy version of the firmware.**

### User Verification Data Injection

**Mitigations:** Use a physically secured user verification input method, e.g. Fingerprint Sensor or Trusted-User-Interface for PIN entry which cannot be by-passed by malware.

**Violates:** SG-1

**Consequences:** This might lead to successful user impersonation (if the attacker has access to valid user verification data).

**Attacker might be able to inject pre-captured user verification data into the Authenticator. For example, if a password is stored in the Authenticator and added reference data known to or reproducible by the attacker.**

### Verification Reference Data Modification

**Mitigations:** [SM-27] Proper protection of the verification reference data and biometric data in the Authenticator.

**Violates:** SG-1

**Consequences:** The attacker would be recognized as the legitimate User and could impersonate the user.

**An attacker gains logical or physical access to the Authenticator and modifies Verification Reference Data (e.g. hashed PIN value, fingerprint templates) stored in the Authenticator and adds reference data known to or reproducible by the attacker.**

### Read access to captured user verification data

**Mitigations:** Limiting access to the user verification data to the Authenticator exclusively.

**Violates:** SG-8

**Consequences:** The attacker gets access to PII and could disclose it violating [SG-8].

**The Attacker gained read access to the captured user verification data (e.g. PIN, fingerprint image, ...).**

### Compromised the internal PRNG state and the entropy source

**Mitigations:** This constitutes a complete compromise of the RNG, with no ability to recover, so mitigation for this threat involves reducing the impact of a compromised RNG. This is partially mitigated by using an allowed random number generator that allows secure integration of additional input [SM-18] and introduction of data derived from the RP challenge additional input to the PRNG, which can help so long as the attacker has not additionally compromised the TLS session or the ASM / Authenticator link. Using the deterministic signature generation methods (e.g., RFC 6979) can reduce the risk of compromise of existing keys during the signature process, as can using the private key and hash of the signed message as additional input to the PRNG during signature generation. Prevention of non-scalable versions of this style of attack is at least partially addressed by [SM-17] and [SM-18].

**Violates:** SG-1, SG-2, SG-3, SG-4, SG-11, SG-14

**Consequences:** May undermine [SG-1], [SG-2], [SG-3], [SG-4], [SG-11], [SG-14].

**In this threat, an attacker compromises the entropy source prior to the Authenticator initially seeding the PRNG during initialization or otherwise compromises the internal PRNG state, and the attacker is able to know or specify all future entropy inputs to the PRNG. No PRNG is able to recover to a secure status under this threat, but it serves as a useful point for comparison.**

### Compromised entropy source after successful seeding during initialization

**Mitigations:** This is mitigated by using an allowed PRNG which retains PRNG state between power cycles; i.e., which conserves PRNG state even when being reseeded [SM-18]. Prevention of non-scalable versions of this style of attack is at least partially addressed by [SM-17] and [SM-18].

**Violates:** SG-1, SG-2, SG-3, SG-4, SG-11, SG-14

**Consequences:** May undermine [SG-1], [SG-2], [SG-3], [SG-4], [SG-11], [SG-14].

**In this threat, an attacker gains the ability to influence the Authenticator’s entropy source, but only after the initial seeding has been conducted (e.g. if initial seeding occurred prior to the attack and / or as per-Authenticator factory injection of entropy).**

### Compromised the internal PRNG state, but not the entropy source

**Violates:**

**In this threat, an attacker compromises the entropy source prior to seeding the PRNG or otherwise compromises the internal PRNG state, but then at some point, the attacker no longer can access / control the entropy source.**
### T-1.4.17 Compromised the internal PRNG state, but not the entropy source

**Mitigations:** This can be mitigated by Authenticators reseeding periodically from an internal entropy source [SM-18]. As a note, this imposes a total number of random number generator requests prior to a required reseed event; in the event that the Authenticator does not have an entropy source internally, this may act as a hard limit on the number of registrations / authentications that such an Authenticator can perform. Prevention of non-scalable versions of this style of attack is at least partially addressed by [SM-17] and [SM-18].

</tbody>
</table>

**Mitigations:**
- This threat is mitigated by using allowed cryptographic primitives.

**Consequences:**
- May undermine security measures.

---

**Fault induced by malformed input**

In this threat, the Authenticator behaves in an unexpected fashion due to an error in processing malformed input. The result of this style of attack is poorly controllable, absent strong internal segmentation of the Authenticator.

**Mitigations:**

**Consequences:**
- May undermine security measures.

---

**Hostile ASM / Client**

In this threat, the Authenticator support infrastructure is hostile, and can feed arbitrary data to the Authenticator.

**Mitigations:**
- This threat is mitigated by SM-10, SM-13.

**Consequences:**
- May undermine security measures.

---

**Compromise of Protected Information**

In this threat, an attacker recovers data that should be protected by the Authenticator.

**Mitigations:**
- This threat is mitigated by using allowed cryptographic primitives.

**Consequences:**
- May undermine security measures.

---

**Signature or registration counter non-monotonicity**

In this threat, an attacker may be able to cause these counters to be reset, to roll over, or otherwise to decrease in value.

**Mitigations:**
- This threat is mitigated by SM-15.

**Consequences:**
- May undermine security measures.

---

**Remote Timing Attacks**

In this threat, an attacker may be able to extract keys using a timing attack from a remote location. The impact depends on the key or secret recovered.

**Mitigations:**
- This threat is mitigated by the remote timing attack resistance security measure.

**Consequences:**
- May undermine security measures.

---

**Fault Injection Attack**

In this threat, an attacker subjects the Authenticator to conditions that induce hardware faults (e.g., exposure to photons or charged particles, inducing variations in supply voltage or external clock, altering the temperature, etc.) in an attempt to subvert some logical or physical protection. The result of this style of attack is poorly controllable, absent active detection and response functionality within the Authenticator. This is related to T-1.4.21, but applies more broadly.

**Mitigations:**

**Consequences:**
- May undermine security measures.

---

**Compromise of Protected Information**

In this threat, an attacker recovers data that should be protected by the Authenticator.

**Mitigations:**
- This threat is mitigated by using allowed cryptographic primitives.

**Consequences:**
- May undermine security measures.

---

**Signature or registration counter non-monotonicity**

In this threat, an attacker may be able to cause these counters to be reset, to roll over, or otherwise to decrease in value.

**Mitigations:**
- This threat is mitigated by SM-15.

**Consequences:**
- May undermine security measures.

---

**Hostile ASM / Client**

In this threat, the Authenticator support infrastructure is hostile, and can feed arbitrary data to the Authenticator.

**Mitigations:**
- This threat is mitigated by SM-10, SM-13.

**Consequences:**
- May undermine security measures.

---

**Debug Interface**

In this threat, the Authenticator has a hardware or software debugging interface that is not completely disabled prior to distribution of the Authenticator (e.g., pads for a JTAG port).

**Mitigations:**
- This threat is mitigated by SM-18, SM-22, and SM-28.

**Consequences:**
- May undermine security measures.

---

**Fault induced by malformed input**

In this threat, the Authenticator behaves in an unexpected fashion due to an error in processing malformed input. The result of this style of attack is poorly controllable, absent strong internal segmentation of the Authenticator.

**Mitigations:**

**Consequences:**
- May undermine security measures.

---

**Fault Injection Attack**

In this threat, an attacker subjects the Authenticator to conditions that induce hardware faults (e.g., exposure to photons or charged particles, inducing variations in supply voltage or external clock, altering the temperature, etc.) in an attempt to subvert some logical or physical protection. The result of this style of attack is poorly controllable, absent active detection and response functionality within the Authenticator. This is related to T-1.4.21, but applies more broadly.

**Mitigations:**

**Consequences:**
- May undermine security measures.

---

**Remote Timing Attacks**

In this threat, an attacker may be able to extract keys using a timing attack from a remote location. The impact depends on the key or secret recovered.

**Mitigations:**
- This threat is mitigated by the remote timing attack resistance security measure.

**Consequences:**
- May undermine security measures.

---

**Compromise of Protected Information**

In this threat, an attacker recovers data that should be protected by the Authenticator.

**Mitigations:**
- This threat is mitigated by using allowed cryptographic primitives.

**Consequences:**
- May undermine security measures.

---

**Hostile ASM / Client**

In this threat, the Authenticator support infrastructure is hostile, and can feed arbitrary data to the Authenticator.

**Mitigations:**
- This threat is mitigated by SM-10, SM-13.

**Consequences:**
- May undermine security measures.
### 7.1.6 Threats to the Secure Channel between Client and Relying Party

#### 7.1.6.1 Exploiting Weaknesses in the Secure Transport of FIDO Messages

FIDO takes as a base assumption that [SA-3] applications on the user device are able to establish secure channels that provide trustworthy server authentication, and confidentiality and integrity for messages, e.g., through TLS. [T-1.2.4] Discusses some consequences of violations of this assumption due to implementation errors in a browser or client application, but other threats exist in different layers.

### 2.1.1 FIDO Server DB Read Attack

**Attacker could obtains read-access to FIDO Server registration database.**

**Consequences:** Attacker can access all cryptographic key handles and authenticator characteristics associated with a username. If an authenticator or combination of authenticators is unique, they might use this to try to violate [SG-2] Unlinkability.

**Mitigations:** [SM-2] Unique Authentication Keys help prevent disclosed key material from being useful against any other Relying Party, even if successfully attacked. The use of an [SM-6] Cryptographically Secure Verifier Database helps assure that it is infeasible to attack any leaked verifier keys.

[SM-9] Authenticator Certification along with [SM-16] should help prevent authenticators with poor entropy from entering the market, reducing the likelihood that even a large corpus of key material will be useful in mounting attacks.

### 2.1.2 FIDO Server DB Modification Attack

**Attacker gains write-access to the FIDO Server registration database.**

**Consequences:** Violation of [SA-6]

The attacker may inject a key registration under its control, violating [SG-1] Strong User Authentication.

**Mitigations:** Mitigating such attacks is outside the scope of the FIDO specifications. The Relying Party must maintain the integrity of any information it relies up on to identify a user as part of [SA-6].

### 2.2.1 Web App Malware

**Attacker gains ability to execute code in the security context of the Relying Party web application or FIDO Server.**

**Consequences:** Attacker is able to violate [SG-1], [SG-10], [SG-9] and any other Relying Party controls.

**Mitigations:** The consequences of such an incident are limited to the relationship between the user and that particular Relying Party by [SM-1], [SM-2], and [SM-5]. Even within the Relying Party to user relationship, a user can be protected by [SM-10] Transaction Confirmation if the compromise does not include the users' computing environment.

### 2.2.2 Linking through compromised Relying Party database

**In this threat, a Relying Party is able to access another Relying Party's database (either because the Relying Parties are collaborating or because of the compromise of another Relying Party's database). The malicious party then sends Key Handles (which may contain a wrapped private key) from the other Relying Party's database in an attempt to link the two separate accounts to the same Authenticator (thus user).**

**Consequences:** May undermine [SG-1], [SG-4].

**Mitigations:** This threat is mitigated by [SM-1], [SM-2], [SM-5], [SM-23].

### 3.1.1 TLS Proxy

**The FIDO user device is administratively configured to connect through a proxy that terminates TLS connections. The client trusts this device, but the connection between the user and FIDO server is no longer end-to-end secure.**

**Consequences:** Any such proxies introduce a new party into the protocol. If this party is untrustworthy, consequences may be as for [T-1.2.4].

**Mitigations:** Mitigations for [T-1.2.4] apply, except that the proxy is considered trusted by the client, so certain methods of [SM-12] Channel Binding may indicate a compromised channel even in the absence of an attack. Servers should use multiple methods and adjust their risk scoring appropriately. A trustworthy client that reports a server certificate that is unknown to the server and does not chain to a public root may indicate a client behind such a proxy. A client reporting a server certificate that is unknown to the server but validates for the server's identity according to commonly used public trust roots is more likely to indicate [T-3.1.2].

### 3.1.2 Fraudulent TLS Server Certificate

**An attacker is able to obtain control of a certificate credential for a Relying Party, perhaps from a compromised Certification Authority or poor protection practices by the Relying Party.**

**Consequences:** As for [T-1.2.4].
7.1.7.3 Threats to the Infrastructure

7.1.7.1 Threats to FIDO Authenticator Manufacturers

7.1.7.2 Threats to FIDO Server Vendors

7.1.7.3 Threats to FIDO Metadata Service Operators

### 7.1.8 Threats Specific to Second Factor Authenticators (UAF / U2F)

#### T-5.1.1 Error Status Side Channel

|        | Relying parties issues an authentication challenge to an authenticator and can infer from error status if it is already registered. |
|        | **Consequences:** UAF Silent authenticators / U2F authenticators not requiring user interaction for generating a signed response may be used to track users without their consent by issuing a pre-authentication challenge to them, revealing the identity of an otherwise anonymous user. Users would be identifiable by relying parties without their knowledge, violating [SG-7]. |
|        | **Mitigations:** The U2F specification recommends that browsers prompt users whether to allow this operation using mechanisms similar to those defined for other privacy sensitive operations like Geolocation. |

#### T-5.1.2 Malicious RP

|        | Malicious relying party mounts a cryptographic attack on a key handle it is storing. |
|        | **Consequences:** If the Relying Party is able to recover the contents of the key handle, it might forge logs of protocol exchanges to associate the user with actions he or she did not perform. |
|        | AC1 If the Relying Party is able to recover the key used to wrap a key handle, that key is likely used for all key handles, and hence might be used to decrypt key handles stored with other Relying Parties and violate [SG-1] Strong User Authentication. |
|        | **Mitigations:** None. U2F depends on [SA-1] to hold for key wrapping operations. |

#### T-5.1.3 Physical Attack on a User Presence Authenticator

|        | Attacker gains physical access to U2F authenticator or a UAF authenticator with only user presence check (e.g., by stealing it). |
|        | **Consequences:** Same as for [T-1.4.4]. |
|        | Such authenticators have weak local user verification. If the attacker can guess the username and password/PIN, they can impersonate the user, violating [SG-1] Strong User Authentication. |
|        | **Mitigations:** Relying Parties can use strong additional factors. Relying Parties should provide users a means to revoke keys associated with a lost device. |

#### T-5.1.4 Physical Attack

|        | In this threat, keys or other sensitive information is read out by directly accessing it from the authenticator that the attacker has physically compromised. |
|        | **Consequences:** May undermine [SG-1], [SG-4], [SG-11], [SG-14]. |
|        | Authenticator with user presence check have weak local user verification. If the attacker can guess the username and password/PIN, they can impersonate the user, violating [SG-1] Strong User Authentication. |
|        | **Mitigations:** Mitigated by resistance to injected faults [SM-18] and [SM-28]. |
